1 ELECTROMAGNETICALLY ACTUATABLE VALVE

2

3

4

5

6 The invention relates to an electromagnetically actuatable valve, in particular for
7 use in motor vehicles according to the preamble of Claim 1.

8

9 Related Art

10

11 Electromagnetic valves are made known in the related art, in which the opening
12 and closing of the valve is achieved by means of a moveable solenoid plunger.
13 The disadvantage of this is that, due to the structural arrangement of the
14 components in such valves, an air gap results between coil and center pole,
15 between solenoid plunger and coil, and between solenoid plunger and center
16 pole, which leads to a marked loss of magnetic flux. A further disadvantage of the
17 traditional electromagnetic valves is that, when the valve opens and closes, the
18 solenoid plunger, which is made of iron, strikes the center pole of the magnetic
19 coil and produces a clearly audible noise.

20

21 Object of the present invention is to create an electromagnetically actuatable
22 valve of the type described in the preamble of Claim 1 that is low-noise or
23 optimized in terms of noise during opening and closing that simultaneously
24 ensures an improved magnetic flux and also saves space.

25

26 This object is solved according to the invention using the subject matter of Claim
27 1. Advantageous embodiments of the subject matter according to the invention
28 are listed in subclaims 2 through 10.

29

30

Advantages of the Invention

The electromagnetically actuatable valve according to the invention has a magnet part, a moveable armature element, a spring element, and a valve part. The magnet part includes at least one magnetic coil wound on a coil form, a flux concentrating element, and a center pole. The valve part has a closing element that cooperates with the armature element and controls the opening and closing of the valve on a valve seat.

10 According to the present invention, the armature element of the valve is designed
11 as a clapper-type armature. The use of a clapper-type armature is advantageous,
12 on the one hand, because the entire electromagnetically actuatable valve can
13 then be designed to be smaller in size than when a traditional solenoid plunger is
14 used. This space-saving design of the valve expands its potential uses. On the
15 other hand, the use of a clapper-type armature involves a better efficiency of the
16 magnetic circuit, which is caused, among other things, by the resultant improved
17 possibility of arranging the clapper-type armature relative to the other
18 components of the valve, whereby air gaps that inhibit magnetic flux are largely
19 avoided and only occur between center pole and armature element.

21 Moreover, the clapper-type armature according to the invention cooperates with
22 the center pole by way of a damping element so that unpleasant noises are
23 prevented when the valve opens and closes. This is particularly important when
24 the electromagnetically actuatable valve is situated in the passenger
25 compartment of a motor vehicle, e.g., in the seats, to vary the seat surface.

27 The armature element and the valve part are preferably located in a housing. The
28 armature element, the flux concentrating element, the closing element, the spring
29 element as well as the damping element are confined in the housing in pressure-
30 sealed fashion. This can be achieved by pressure-sealed injection of the flux
31 concentrating element. All sensitive components of the valve are therefore

protected. The housing can also be designed to be two-piece or multi-piece and
be permanently joined by gluing the housing parts together, for example.

4 In a further preferred embodiment, the electromagnetically actuatable valve has a
5 damping element with a damping stop which absorbs sound, so noise is reduced
6 when the valve opens and closes.

Moreover, the flux concentrating element is preferably designed as a bracket which is situated on the perimeter of the magnetic coil.

10
11 In yet another preferred embodiment, the armature element actuates a closing
12 element to open and close the valve, which closing element is designed as an
13 umbrella sealing plug with an umbrella membrane. The umbrella sealing plug is
14 flexible and preferably made out of silicone rubber. As a result, when the clapper-
15 type armature, which is made of iron, strikes the umbrella sealing plug to open
16 the valve, noise is reduced considerably.

17
18 The damping element and the closing element can preferably be designed as an
19 integral damping shoe, which also consists entirely of an elastic material such as
20 silicone rubber. This damping shoe can be attached directly to the armature
21 element or it can be injection moulded to it. This embodiment is particularly
22 practical, because the absorption of the sound caused by the striking of the
23 clapper-type armature when the valve opens as well as when it closes can be
24 achieved using the same device, which can be easily and quickly attached to the
25 clapper-type armature by sliding it into place, or it has already been injection
26 moulded to it.

Drawing

30 Two preferred embodiments of the clapper-type armature are shown in the
31 drawings, which are explained in greater detail using the description below.

1
2 Figure 1 shows a schematic diagram of a cross-sectional view of the
3 electromagnetically actuatable valve according to the invention, and
4 Figure 2 shows a schematic diagram of a cross-sectional view of a preferred
5 embodiment of the electromagnetically actuatable valve according to the
6 invention.

7
8 Figure 1 shows a schematic diagram of an electromagnetically actuatable valve 1
9 in cross section which has a magnet part 2, which includes a coil form 3 on which
10 a magnetic coil 4 is wound, as well as a perpendicular flux concentrating element
11 5 on the perimeter of the coil form 3, and a center pole 6 situated inside the coil
form 3. Moreover, the valve 1 has a valve part 9 having a closing element 11.
12 The closing element 11 for opening and closing the valve 1 cooperates with an
13 armature element 7 on a valve seat 10, whereby the armature element 7 is
14 designed as a clapper-type armature. The armature element is thereby situated
15 on a face of the magnet part perpendicular to the longitudinal axis of the center
16 pole 6 and is connected with the flux concentrating element 5. To open the valve,
17 the armature element 7 is pulled through an induced magnetic field in the
18 direction of the center pole. The closing element is an umbrella sealing plug with
19 an umbrella membrane that makes it possible for a fluid to flow through the valve
20 channel when the armature element 7 is picked up. The umbrella stopper
21 consists of a flexible material such as silicone rubber. Moreover, a head 18
22 designed on the center pole 6 is provided with a damping element 14 that has a
23 damping stop 13. The armature element 7 is held on a spring element 8 on the
24 side opposite to the side actuating the closing element. The spring element 8 is a
25 spiral-coiled spring that returns the armature element 7 to its position that closes
26 the valve.
27

28
29 The spring element 8, a section of the flux concentrating element 5, the armature
30 element 7, the head of the center pole 18 as well as the closing element 11 are
31 contained in a housing. The housing comprises an upper housing section 16 that

1 touches the coil form 3, and a lower housing section 17 in which two openings
2 19—one inlet opening and one outlet opening—and the valve seat 10 are
3 located. The upper housing section 16 and the lower housing section 17 are
4 permanently connected with each other and form a pressure-sealed
5 compartment. The valve seat is generally a component of the lower housing 17.

6

7 Figure 2 also shows a schematic diagram of an electromagnetically actuatable
8 valve 1 in cross section, whereby the magnet part of the valve 1 has the same
9 design as the one described in Figure 1. It differs, however, in that the closing
10 element 11 and the damping stop 13 are designed single-piece as a damping
11 shoe 15. The damping shoe 15 is attached directly to the armature element 7 or
12 it is injection moulded to it. Moreover, a leaf spring is used as the spring element
13 8, which is attached to an end section of the flux concentrating element 5
14 extending into the housing and to a section of the armature element 7. The layout
15 of the housing as well as the arrangement of the components of the
16 electromagnetically actuatable valve 1 included therein correspond to those in
17 Figure 1.
